Medication allergies are common!

8% of patients treated as outpatients and 20% of hospitalised patients show adverse drug reactions. In 80% of cases these are not allergies but rather adverse ‘side effects’ of the active substance. Nevertheless, the fraction of true medication allergies is still considerable at 20%. Unlike other side effects, an allergy involves inflammatory reactions that are induced by interactions between medication components or metabolites and allergen-specific antibodies or immune cells. In principle, every preparation even those that do not require a prescription) can cause an allergy.

An allergic reaction to medications cannot be predicted. Patients with known atopic disposition do not suffer more often from medication allergies. On the other hand, medication allergies can occur in patients with a completely normal allergy history. It is only known that patients with systemic viral infections react more frequently to antibiotics (e.g., ampicillin with mononucleosis).

Manifestations of medication allergy

The symptoms of a medication allergy are determined by the particular pathomechanisms which are divided into 4 types according to Coombs and Gell. Allergy types I and IV dominate (see table). A special form is the pseudoallergy which has symptoms that resemble those of type I allergies but which is not triggered by IgE antibodies and is therefore not detected by IgE or epicutaneous testing.

The symptoms of a medication allergy depend on the allergy type present.

There are allergies of type I to type IV.

Type I (IgE mediated): Urticaria, rash, weals, erythroderma, rhinitis, asthma and anaphylaxis

Type II (IgG/complement mediated): Granulocyto-paenia, erythrocytopaenia, lymphocytopaenia

Type III (IgM/complement mediated): Vasculitis, arthritis, glomerulonephritis

Type IV (T lymphocyte mediated): Skin eczema, hepatitis (liver values ↑), nephritis, flu-like symptoms

Diagnosis of medication allergy of type I and type IV

The diagnostics include a medical history, clinical results, skin tests and the laboratory diagnostics. Provocation tests are, with the exception of ASA intolerance, are usually omitted with medication allergies.

Depending on the symptoms (see above) and primarily on their development over time (< 24 hours usually type I; > 24 hours more likely to be type IV), the basophil degranulation test (BDT) and/or the lymphocyte transformation test (LTT) will be done in the laboratory. These test procedures are in vitro provocation tests, that is, the blood cells of the patient (lymphocytes for the LTT or basophils for the BDT) are ‘provoked’ with the suspected allergen in the laboratory. The BDT (synonyms: CAST test, basophil activation test) measures the release of leukotrienes and the LTT measures lymphocyte activation as ‘evidence’ that there is an individual sensitisation.

In both laboratory tests there is the option of testing active substances that are available in the laboratory but native substances (e.g., tablets, capsules, injection solutions) can also be sent with the blood sample to the laboratory.

**Sample results:**

- **Evidence of a type IV sensitisation to amoxicillin.** The reason behind the diagnosis was ‘general feeling of malaise’ and an increase in the liver values GPT and GOT. There were no skin symptoms present.

**Sample results:**

- **Evidence of an NSAID hypersensitivity to aspirin [ASA] and diclofenac but not to ibuprofen.**
Diag-Info: 108 Version: 4

IgE determination is less helpful

Determining the specific IgE in the serum is common for inhalation allergies, but is not really helpful with suspected medication allergies, because it can only be used with a few active substances (testing of native preparations is not possible) and type IV allergies are not detected. The exceptions are, if required, IgE antibodies to penicillin and penicillin derivatives (rarely false positive) which are only moderately sensitive, however (often false negative). The following applies therefore: a positive IgE test is an indication of sensitisation but a negative test does not rule one out.

Type II and type III allergies are difficult to verify

IgG- and/or IgM-mediated type II and type III allergies cannot be proven using laboratory diagnostics. Allergen-specific IgG and IgM antibodies cannot be detected, because they are not formed against the medication itself but rather against cellular structures modified by the medication. These are not accessible to allergy testing. With sudden cytopenia in the blood count, a type II allergy should be considered and with vasculitis, sudden onset arthritis or glomerulonephritis a possible type III allergy should be considered.

What are pseudoallergies?

Pseudoallergies (idiosyncratic reactions), which are clinically very similar to type I allergies, are also possible. In the majority of cases these are caused by the active substance or an additive or preservative ‘switching on’ the activation cascade of mast cells without a prior IgE-receptor-mediated activation [therefore ‘pseudo…’]. Pseudoallergies can be verified with laboratory diagnostics using the basophil degranulation test (BDT).

Materials required

BDT
2 ml EDTA or heparin blood per medication

LTT
5 ml heparin blood per medication plus [one-off]
5 mL whole blood [serum].

Please request the LTT blood sampling material free of charge on [030] 770 01–220

The following active substances are available in the laboratory for testing:

**Antibiotics**
Amoxicillin, ampicillin, cefazolin, cefuroxime, ciprofloxacin, clarithromycin, penicillin, rifampicin, sulfamethoxazole, trimethoprim, tetracycline

**Pain relief**
Aspirin/acetysalicylic acid, diclofenac, ibuprofen, indomethacin, mefenamic acid, metamizole, paracetamol, phenylbutazone, propyphenazona

**Anaesthetics**
Lidocaine, mepivacaine, articaine, prilocaine, ubistesin

**Muscle relaxants**
Atracurium, mivacurium, pancuronium, propofol, rocuronium, suxamethonium, vecuronium.

Preparations not listed here should be sent with the blood samples (a blistered tablet or capsule, an ampoule; please do not send filled containers due to the risk of contamination).

Invoicing

**BDT:** 51,29 € per medication
**LTT:** 56,53 € per medication
